

System Generator for DSP

Getting Started Guide

Release 10.1.3 September, 2008

Xilinx is disclosing this Document and Intellectual Property (hereinafter "the Design") to you for use in the development of designs to operate on, or interface with Xilinx FPGAs. Except as stated herein, none of the Design may be copied, reproduced, distributed, republished, downloaded, displayed, posted, or transmitted in any form or by any means including, but not limited to, electronic, mechanical, photocopying, recording, or otherwise, without the prior written consent of Xilinx. Any unauthorized use of the Design may violate copyright laws, trademark laws, the laws of privacy and publicity, and communications regulations and statutes.

Xilinx does not assume any liability arising out of the application or use of the Design; nor does Xilinx convey any license under its patents, copyrights, or any rights of others. You are responsible for obtaining any rights you may require for your use or implementation of the Design. Xilinx reserves the right to make changes, at any time, to the Design as deemed desirable in the sole discretion of Xilinx. Xilinx assumes no obligation to correct any errors contained herein or to advise you of any correction if such be made. Xilinx will not assume any liability for the accuracy or correctness of any engineering or technical support or assistance provided to you in connection with the Design.

THE DESIGN IS PROVIDED "AS IS" WITH ALL FAULTS, AND THE ENTIRE RISK AS TO ITS FUNCTION AND IMPLEMENTATION IS WITH YOU. YOU ACKNOWLEDGE AND AGREE THAT YOU HAVE NOT RELIED ON ANY ORAL OR WRITTEN INFORMATION OR ADVICE, WHETHER GIVEN BY XILINX, OR ITS AGENTS OR EMPLOYEES. XILINX MAKES NO OTHER WARRANTIES, WHETHER EXPRESS, IMPLIED, OR STATUTORY, REGARDING THE DESIGN, INCLUDING ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT OF THIRD-PARTY RIGHTS.

IN NO EVENT WILL XILINX BE LIABLE FOR ANY CONSEQUENTIAL, INDIRECT, EXEMPLARY, SPECIAL, OR INCIDENTAL DAMAGES, INCLUDING ANY LOST DATA AND LOST PROFITS, ARISING FROM OR RELATING TO YOUR USE OF THE DESIGN, EVEN IF YOU HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. THE TOTAL CUMULATIVE LIABILITY OF XILINX IN CONNECTION WITH YOUR USE OF THE DESIGN, WHETHER IN CONTRACT OR TORT OR OTHERWISE, WILL IN NO EVENT EXCEED THE AMOUNT OF FEES PAID BY YOU TO XILINX HEREUNDER FOR USE OF THE DESIGN. YOU ACKNOWLEDGE THAT THE FEES, IF ANY, REFLECT THE ALLOCATION OF RISK SET FORTH IN THIS AGREEMENT AND THAT XILINX WOULD NOT MAKE AVAILABLE THE DESIGN TO YOU WITHOUT THESE LIMITATIONS OF LIABILITY.

The Design is not designed or intended for use in the development of on-line control equipment in hazardous environments requiring fail-safe controls, such as in the operation of nuclear facilities, aircraft navigation or communications systems, air traffic control, life support, or weapons systems ("High-Risk Applications"). Xilinx specifically disclaims any express or implied warranties of fitness for such High-Risk Applications. You represent that use of the Design in such High-Risk Applications is fully at your risk.

About This Guide

This Getting Started Guide introduces you to **System Generator for DSP**, then provides installation and configuration instructions, release information, and six mini-training modules that highlight the main features of the product. Each module starts with a lesson of 8-10 slides that explain important concepts, followed by a lab exercise that take about 30 minutes to complete. Because this introductory training is part of the tool, you can progress through the material at your own pace and on your own time schedule

Guide Contents

This Getting Started Guide contains the following topics:

- Introduction
- Installation
- Release Information
- Getting Started
 - a. Design Creation Basics
 - b. Fixed Point and Bit Operations
 - c. System Control
 - d. Multi-Rate Systems
 - e. Using Memories
 - f. Designing Filters
 - g. Additional Examples and Tutorials

System Generator PDF Doc Set

This Getting Started Guide can be found in the System Generator Help system and is also part of the System Generator Doc Set that is provided in PDF format. The content of the doc set is as follows:

- *System Generator for DSP Getting Started Guide*
- *System Generator for DSP User Guide*
- *System Generator for DSP Reference Guide*

Note: Hyperlinks across these PDF documents work only when the PDF files reside in the same folder. After clicking a Hyperlink in the Adobe Reader, you can return to the previous page by pressing the Alt key and the left arrow key (←) at the same time.

Additional Resources

To find additional documentation, see the Xilinx website at:

<http://www.xilinx.com/literature>.

To search the Answer Database of silicon, software, and IP questions and answers, or to create a technical support WebCase, see the Xilinx website at:

<http://www.xilinx.com/support>.

Conventions

This document uses the following conventions. An example illustrates each convention.

Typographical

The following typographical conventions are used in this document:

Convention	Meaning or Use	Example
Courier font	Messages, prompts, and program files that the system displays	speed grade: - 100
Courier bold	Literal commands that you enter in a syntactical statement	ngdbuild <i>design_name</i>
Helvetica bold	Commands that you select from a menu	File → Open
	Keyboard shortcuts	Ctrl+C
Italic font	Variables in a syntax statement for which you must supply values	ngdbuild <i>design_name</i>
	References to other manuals	See the <i>Development System Reference Guide</i> for more information.
	Emphasis in text	If a wire is drawn so that it overlaps the pin of a symbol, the two nets are <i>not</i> connected.
Square brackets []	An optional entry or parameter. However, in bus specifications, such as bus [7 : 0] , they are required.	ngdbuild [<i>option_name</i>] <i>design_name</i>
Braces { }	A list of items from which you must choose one or more	lowpwr = { on off }
Vertical bar	Separates items in a list of choices	lowpwr = { on off }

Convention	Meaning or Use	Example
Vertical ellipsis . . .	Repetitive material that has been omitted	IOB #1: Name = QOUT' IOB #2: Name = CLKIN' . . .
Horizontal ellipsis ...	Repetitive material that has been omitted	allow block <i>block_name loc1 loc2 ... locn;</i>

Online Document

The following conventions are used in this document:

Convention	Meaning or Use	Example
Blue text	Cross-reference link to a location in the current document	See the topic " Additional Resources " for details. Refer to " Title Formats " in Chapter 1 for details.
Red text	Cross-reference link to a location in another document	See Figure 2-5 in the <i>Virtex-II Platform FPGA User Guide</i> .
Blue, underlined text	Hyperlink to a website (URL)	Go to http://www.xilinx.com for the latest speed files.

Introduction

System Generator is a DSP design tool from Xilinx that enables the use of The Mathworks model-based design environment Simulink for FPGA design. Previous experience with Xilinx FPGAs or RTL design methodologies are not required when using System Generator. Designs are captured in the DSP friendly Simulink modeling environment using a Xilinx specific blockset. All of the downstream FPGA implementation steps including synthesis and place and route are automatically performed to generate an FPGA programming file.

The Xilinx DSP Block Set

Over 90 DSP building blocks are provided in the Xilinx DSP blockset for Simulink. These blocks include the common DSP building blocks such as adders, multipliers and registers. Also included are a set of complex DSP building blocks such as forward error correction blocks, FFTs, filters and memories. These blocks leverage the Xilinx IP core generators to deliver optimized results for the selected device.

FIR Filter Generation

System Generator includes a FIR Compiler block that targets the dedicated DSP48 hardware resources in the Virtex™-4 and Virtex™-5 devices to create highly optimized implementations that can run in excess of 500 Mhz. Configuration options allow generation of direct, polyphase decimation, polyphase interpolation and oversampled implementations. Standard MATLAB functions such as fir2 or The Mathworks Fdatool can be used to create coefficients for the Xilinx FIR Compiler.

FDA Tool

Support for MATLAB

Algorithmic MATLAB models can be incorporated into System Generator through AccelDSP™. AccelDSP includes powerful algorithmic synthesis that takes floating-point MATLAB as input and generates a fully scheduled fixed-point model for use with System Generator. Features include floating- to fixed-point conversion, Automatic IP insertion, design exploration and algorithmic scheduling. Also included in System Generator is an MCode block that allows the use of non-algorithmic MATLAB for the modeling and implementation of simple control operations.

System Resource Estimation

System Generator provides a Resource Estimator block that quickly estimates the area of a design prior to place and route. This can be a valuable aid in the hardware / software partitioning process by helping system designers take full advantage of the FPGA resources which include up to 640 multiply/accumulate (or DSP) blocks in the Virtex™-5 devices.

The screenshot shows the 'Resource Estimator (Xilinx Resource Estimat...)' dialog box. It contains several input fields for resource counts: Slices (380), FFs (682), BRAMs (0), LUTs (610), IOBs (100), Emb. Mults (0), and TBUFs (0). Below these fields is a checkbox labeled 'Use area above' which is currently unchecked. At the bottom, there is an 'Estimate options' dropdown menu set to 'Estimate', followed by an 'Estimate' button. At the very bottom are four buttons: 'OK', 'Cancel', 'Help', and 'Apply'.

Resource Type	Value
Slices	380
FFs	682
BRAMs	0
LUTs	610
IOBs	100
Emb. Mults	0
TBUFs	0

☐ Use area above

Hardware Co-Simulation

System Generator provides accelerated simulation through hardware co-simulation. System Generator will automatically create a hardware simulation token for a design captured in the Xilinx DSP blockset that will run on one of over 20 supported hardware platforms. This hardware will co-simulate with the rest of the Simulink system to provide up to a 1000x simulation performance increase.

System Integration Platform

System Generator provides a system integration platform for the design of DSP FPGAs that allows the RTL, Simulink, MATLAB and C/C++ components of a DSP system to come together in a single simulation and implementation environment. System Generator supports a black box block that allows RTL to be imported into Simulink and co-simulated with either ModelSim or Xilinx ISE™ Simulator. System Generator also supports the inclusion of a MicroBlaze™ embedded processor running C/C++ programs.

Installation

Downloading

System Generator is only available via download from the Xilinx web page. You may purchase, register, and download the System Generator software from the site at:

http://www.xilinx.com/ise/optional_prod/system_generator.htm

Note: In special circumstances, System Generator can be delivered on a CD. Please contact your Xilinx distributor if your circumstances prohibit you from downloading the software via the web.

Hardware Co-Simulation Support

If you have an FPGA development board, you may be able to take advantage of System Generator's ability to use FPGA hardware co-simulation with Simulink simulations. The System Generator software includes support for the XtremeDSP Development Kit, the MicroBlaze™ Multimedia Demonstration boards, the MVI hardware platform, the ML402 Virtex™-4 platform, the ML506 Virtex™-5 platform, and the Spartan-3A DSP 1800 starter platform and 3400 development platform. Additional System Generator board support packages provide support for additional hardware co-simulation platforms. System Generator board support packages can be downloaded from the following URL:

http://www.xilinx.com/technology/dsp/thirdparty_devboards.htm

Installing

Software Prerequisites

You must have the following software installed before running System Generator.

- One of the following versions of MATLAB from The MathWorks Inc:
 - MATLAB v7.4/Simulink v6.6 (R2007a)
 - MATLAB v7.5/Simulink v7.0 (R2007b)
- Note:** MATLAB must be installed in a directory with no spaces (e.g., C:\MATLAB\R2007a).
- Xilinx ISE™ Foundation™ version 10.1

Some features in System Generator require the following software to be installed:

- A logic synthesis tool. System Generator is fully compatible with Xilinx XST (included in the ISE Foundation bundle) and Synplify Pro v8.6.2 or v8.9 from Synplicity, Inc.
- A hardware description language (HDL) simulator is required only for co-simulating HDL modules within Simulink using System Generator. System Generator HDL co-

simulation interfaces are compatible with the Xilinx ISE Simulator, and ModelSim SE from Model Technology Inc.

Note: The Microsoft Windows environment variable \$XILINX must be set and point to your ISE software installation directory.

ISE software service packs may be downloaded from the Xilinx Download Center:

http://www.xilinx.com/xlnx/xil_sw_updates_home.jsp

Using the ISE Design Suite Installer

Before invoking the ISE™ Design Suite Installer, it is a good idea to make sure that all instances of MATLAB are closed. When all instances of MATLAB are closed, launch the installer and follow the directions on the screen.

Choose MATLAB Version for System Generator

As the last step of the System Generator installation, click the check box of the MATLAB installation you wish to associate with this version of System Generator, then click **Apply**.

If you don't see a valid version of MATLAB listed, for example a version installed on a network device, click the **Add Version** button, browse to the MATLAB root directory of the unlisted version, then click **Add**. If you wish to associate this version of MATLAB with System Generator, click the check box of the newly listed MATLAB installation, then click **Apply**.

If you have no version of MATLAB available, click **Choose Later** to continue with the installation. At a later time, after you have installed MATLAB, you can associate that version of MATLAB with System Generator by executing the Windows menu item **Start > All Programs > Xilinx ISE Design Suite 10.1 > DSP Tools > Select MATLAB version for Xilinx System Generator**.

Hardware Co-Simulation Installation

This topic provides links to hardware and software installation procedures for hardware co-simulation. If you do not plan to use hardware co-simulation, you may skip this topic.

Ethernet-Based Hardware Co-Simulation

[Installing an ML402 Platform for Ethernet Hardware Co-Simulation](#)

[Installing an ML506 Platform for Ethernet Hardware Co-Simulation](#)

[Installing a Spartan-3A DSP 1800A Starter Platform for Ethernet Hardware Co-Simulation](#)

[Installing a Spartan-3A DSP 3400A Development Platform for Ethernet Hardware Co-Simulation](#)

Note: If installation instructions for your particular platform are not provided here, please refer to the installation instructions that come with your Platform Kit.

JTAG-Based Hardware Co-Simulation

[Installing an ML402 Board for JTAG Hardware Co-Simulation](#)

Third-Party Hardware Co-Simulation

As part of the Xilinx XtremeDSP™ Initiative, Xilinx works with distributors and many OEMs to provide a variety of DSP prototyping and development platforms. Please refer to

the following Xilinx web site page for more information on available platforms:
http://www.xilinx.com/technology/dsp/thirdparty_devboards.htm

Compiling Xilinx HDL Libraries

If you intend to simulate System Generator designs using ModelSim, you must compile your IP (cores) libraries. This topic describes the procedure.

ModelSim SE

The Xilinx tool that compiles libraries for use in ModelSim SE is named **compplib**. The following command can, for example, be used to compile all the VHDL and Verilog libraries with ModelSim SE:

```
compplib -s mti_se -f all -l all
```

Complete instructions for running compplib can be found in the ISE Software Manual titled "Synthesis and Simulation Design Guide".

Configuring the System Generator Cache

Both the System Generator simulator and the design generator incorporate a disk cache to speed up the iterative design process. The cache does this by tagging and storing files related to simulation and generation, then recalling those files during subsequent simulation and generation rather than rerunning the time consuming tools used to create those files.

Setting the Size

By default, the cache will use up to 500 MB of disk space to store files. To specify the amount of disk space the cache should use, set the `SYSGEN_CACHE_SIZE` environment variable to the size of the cache in megabytes. Set this number to a higher value when working on several large designs.

Setting the Number of Entries

The cache entry database stores a fixed number of entries. The default is 20,000 entries. To set size of the cache entry database, set the `SYSGEN_CACHE_ENTRIES` environment variable to the desired number of entries. Setting this number too small will adversely affect cache performance. Set this number to a higher value when working on several large designs.

Displaying and Changing Versions of System Generator

It is possible to have several versions of System Generator installed. The MATLAB command `xlVersion` displays which versions are installed, and makes it possible to switch from one to another. `xlVersion` is useful when upgrading a model to run in the latest version of System Generator.

Entering "xlVersion" in the MATLAB console displays the versions of System Generator that are installed, and entering "xlVersion <version>" switches to the specified version. For example, if the versions that are installed are 9.2.01 and 10.1, and the currently selected version is 10.1, then entering "xlVersion" displays

```
Available System Generator installations:
Version 9.2.01 in C:/Xilinx/9.2.01/DSP_Tools/sysgen
Version 10.1 in C:/Xilinx/10.1/DSP_Tools/sysgen
Current version of System Generator is 10.1.
```

Entering "xlVersion 9.2.01" switches the System Generator version to 9.2.01.

Occasionally, it is necessary to restart MATLAB to make it possible to switch. In this case, the response to entering "xlVersion 10.1" looks like the following:

```
Please restart MATLAB and run xlVersion 10.1 again to switch.
```

When the switch succeeds, xlVersion prints the following:

```
Your System Generator has been switched. Please restart MATLAB.
```

If you install System Generator 10.1 after you install 9.2.01, you need to install 10.1 again in order to make xlVersion work.

Once you switch System Generator version, you need to switch to the right version of ISE in order to make System Generator work correctly.

Release Information

Release Notes 10.1.3

Xilinx DSP Blockset Enhancements

DSP48 Abstraction for Mathematical Operators

Accumulator, AddSub, and Counter blocks can now be implemented using either a DSP48 or the original LUT-based implementation. This enables design portability across all supported Xilinx devices.

Fast Fourier Transform 6.0

New block now available in System Generator with the following features:

- Extended data and phase factor width to 34 bits
- Block floating-point support available for Pipelined, Streaming I/O architecture

WaveScope

- WaveScope waveforms can now be directly sent to a printer from WaveScope and a “Print Preview” capability allows you to view and customize the waveform formatting before printing. The capability can be accessed via the **File** pull-down menu or a toolbar shortcut.

Tool Flow and Integration

System Generator 10.1.3 is compatible with the following tools:

Tool	Version
The Mathworks MATLAB® and Simulink	2007b and 2008a
Mentor Graphics ModelSim® SE	6.3c
Synplicity Synplify Pro®	8.8.0.4 (Requires a floating license for Hardware Co-Simulation)
Xilinx® AccelDSP	10.1.03
Xilinx® ChipScope Pro	10.1.03
Xilinx® EDK	10.1.03
Xilinx® ISE	10.1.03

Tool	Version
Xilinx® ISE IP Update	10.1 IP Update 3
Xilinx® ISE Simulator	10.1.03

Known Issues

Known issues with System Generator can be found at the following Xilinx web site address:

<http://www.xilinx.com/support/answers/29595.htm>

Release Notes 10.1.2

System Generator Enhancements

Hybrid DCM-CE Support

In the 10.1 release, System Generator introduced a new clocking option to automatically include a DCM (Digital Clock Manager) in a design. This option was limited to designs with no more than three clock rates.

In this release, this clocking option has been enhanced to support designs with more than three clock rates. The additional rates are automatically supported with the CE (Clock Enable) methodology. For example, if a design has six clock rates, the highest three clock rates are supported with a DCM and the lowest three clock rates are supported with the CE methodology.

MATLAB 2008a

MATLAB 2008a is now supported by System Generator.

Xilinx DSP Blockset Enhancements

FIR Compiler 4.0

New block now available in System Generator with the following features.

- Extended data and coefficient width range up to 49 bits.
- Polyphase filter bank support for channelizer applications & transpose multiply-accumulate architecture.
- Capability to share control and coefficient memory resources for up to 16 parallel data paths.
- Virtex-5 and Spartan-3A DSP support added for distributed arithmetic architecture.

This block supports all the features supported by FIR Compiler LogiCORE v4.0.

Divider Generator 2.0

New block now available in System Generator that generates arithmetic division algorithms for integer division.

- Optional operand widths up to 54 bit wide, synchronous controls, and selectable latency.
- Supports Virtex-4, Virtex-5 & Spartan3A-DSP for both radix-2 integer division and high-radix division algorithms.

Tool Flow and Integration

System Generator 10.1.2 is compatible with the following tools:

Tool	Version
The Mathworks MATLAB® and Simulink	2007b and 2008a
Mentor Graphics ModelSim® SE	6.3c
Synplicity Synplify Pro®	8.8.0.4 (Requires a floating license for Hardware Co-Simulation)
Xilinx® AccelDSP	10.1.02
Xilinx® ChipScope Pro	10.1.02
Xilinx® EDK	10.1.02
Xilinx® ISE	10.1.02
Xilinx® ISE IP Update	10.1 IP Update 2
Xilinx® ISE Simulator	10.1.02

Known Issues

Known issues with System Generator can be found at the following Xilinx web site address:

<http://www.xilinx.com/support/answers/29595.htm>

Release Notes 10.1.1

System Generator Enhancements

- Enhanced UCF Support for EDK Import Flow
The handling of UCF (User Constraint File) files in the EDK import flow has been enhanced to support larger UCF file sizes. The UCF file of an imported XPS project is now parsed and modified to form a new UCF file based on the settings of the EDK Processor block. The user has the ability to view and modify the original UCF file and then re-import the XPS project.
- Enhanced PLB Dual Clock Support
Xilinx Platform Studio projects that use clock generators to drive the PLB bus, MicroBlaze™ processor and other hardware peripherals with different clocks can now automatically be imported into System Generator for HDL netlisting and hardware co-simulation.

Xilinx DSP Blockset Enhancements

CIC Compiler 1.2

Update to existing block

- Simulation speedup of ~4x as compared to CIC Compiler 1.1

DDS Compiler 2.1

Update to existing block.

- Core generation time has been reduced by ~10x as compared to previous versions of the DDS Compiler.
- Ability to specify negative frequencies.
- In the previous version of the DDS Compiler, after reset has been de-asserted, the RDY output goes high 1-cycle too early; this error has been corrected.

Tool Flow and Integration

System Generator 10.1.1 is compatible with the following tools:

Tool	Version
The Mathworks MATLAB® and Simulink	2007a and 2007b
Mentor Graphics ModelSim® SE	6.3c
Synplicity Synplify Pro®	8.8.0.4 (Requires a floating license for Hardware Co-Simulation)
Xilinx® AccelDSP	10.1.01
Xilinx® ChipScope Pro	10.1.01
Xilinx® EDK	10.1.01
Xilinx® ISE	10.1.01
Xilinx® ISE IP Update	10.1 IP Update 1
Xilinx® ISE Simulator	10.1.01

Known Issues

Known issues with System Generator can be found at the following Xilinx web site address:

<http://www.xilinx.com/support/answers/29595.htm>

Release Notes 10.1

System Generator Enhancements

System Generator / Project Navigator Integration

System Generator designs can now be more easily incorporated into a larger design inside of Project Navigator by using a new source type in Project Navigator. The System Generator design can also be launched from Project Navigator.

DCM Support

System Generator now provides the option to automatically include a DCM in a design. Although the optional DCM is abstracted away from the designer, the generated design will leverage DCMs available in the silicon.

An alternative option exposes the clock ports at the top level for manual connection to a DCM.

Dual Asynchronous-Clock Support for PLB46

This capability gives the designer additional flexibility by allowing the DSP and embedded processing portions of a design to run at different clock rates.

Run Time Speed Improvements

- Up to 2x faster first time initialization of a simulation
- >10x faster initialization when loading the Xilinx Blockset in the Simulink Library Browser

M-Based HW Co-Simulation

System Generator models compiled for HW Co-Simulation can now be embedded, configured and utilized in a MATLAB M-code script; allowing for calls into hardware to be made from MATLAB.

Xilinx DSP Blockset Enhancements

FFT 5.0

Update to existing block which now includes cyclic prefix insertion

FIR Compiler 3.2

Update which now include support for Virtex II and Spartan 3A.

Reset Generator

New block that produces synchronized downsampled reset signals which eliminates the need to manually create these signals.

CIC Compiler 1.1

New block now available in System Generator.

Tool Flow and Integration

System Generator 10.1 is compatible with the following tools:

Tool	Version
The Mathworks MATLAB® and Simulink	2007a and 2007b
Mentor Graphics ModelSim® SE	6.3c
Synplicity Synplify Pro®	8.8.0.4 (Requires a floating license for Hardware Co-Simulation)
Xilinx® AccelDSP	10.1
Xilinx® ChipScope Pro	10.1
Xilinx® EDK	10.1
Xilinx® ISE	10.1
Xilinx® ISE IP Update	10.1 IP Update 1
Xilinx® ISE Simulator	10.1

Known Issues

Known issues with System Generator can be found at the following Xilinx web site address:

<http://www.xilinx.com/support/answers/29595.htm>

Upgrading a Xilinx System Generator Model

Upgrading v2.x and Prior Models

If you are upgrading from versions of System Generator earlier than **v3.1**, you must obtain System Generator v7.x and update your models to v7.x before you can update them to v9.1.01.

Upgrading v3.x, v6.x and v7.x Models

This section describes the process of upgrading a Xilinx System Generator v3.x, v6.x or v7.x model to work with v9.1.01.

Note: Any reference to v3.x or v6.x in this section can be used interchangeably with v7.x.

The basic steps for upgrading a v7.x model to v9.1.01 is as follows: 1) Save a backup copy of your v7.1 model and user-defined libraries that your model uses 2) Run `xlUpdateModel` on any libraries first and then on your model 3) Read the report produced by `xlUpdateModel` and follow the instructions 4) Check that your model runs under v9.1.01.

These steps are described in greater detail below.

1. Save a backup copy of your v7.1 model and user-defined libraries that your model uses.
2. Run the `xlUpdateModel` Function

From the MATLAB console, `cd` into the directory containing your model. If the name of your model is `designName.mdl`, type `xlUpdateModel('designName')`.

The `xlUpdateModel` function performs the following tasks:

- ◆ Updates each block in your v7.x design to a corresponding v9.1.01 block with equivalent settings.
- ◆ Writes a report explaining all of the changes that were made. This report enumerates changes you may need to make by hand to complete the update.

In most cases, `xlUpdateModel` produces an equivalent v9.1.01 model. However, there are a few constructs that may require you to edit your model. It is important that you read the report and follow the remaining steps in this section.

3. Read the `xlUpdateModel` report and Follow the Instructions

If the report contains the issues listed below, manual intervention will be required to complete the conversion.

- a. Xilinx System Generator v7.x models containing removed blocks

The following blocks have been removed from System Generator: CIC, Clear Quantization Error, Digital Up Converter, J.83 Modulator, Quantization Error, Sync.

- b. Xilinx System Generator v7.x Models that Contain Deprecated Blocks

The DDSv4.0 block still exist in System Generator, but has been deprecated:

- c. Xilinx System Generator v7.x Models Utilizing Explicit Sample Periods

The explicit sample period fields have been removed from most non-source blocks in System Generator v9.1.01. Source blocks (e.g., Counter block) continue to allow the specification of explicit sample periods. When upgrading models containing

feedback loops, Assert blocks must typically be added by hand after `xlUpdateModel` has been run. This is necessary in order to help System Generator determine appropriate rates and types for the path. The following error message is an indication that an Assert block is required:

“The data rates could not be established for the feedback paths through this block. You may need to add Assert blocks to instruct the system”

In such a case, you should augment each feedback loop with an Assert block, and specify rates and types explicitly on this block.

The update script will annotate the converted model wherever the v7.1 model asserted an explicit period. In the converted model, you will most often not need to insert Assert blocks. To find out where you need them, try to update the diagram (the Update Diagram control is under the Edit menu). If rates do not resolve, you will need to insert one or more Assert blocks.

The update script can be configured to automatically insert Assert blocks immediately following blocks configured with an explicit sample period setting. To use this option, run the following command:

```
xlUpdateModel(designName, 'assert')
```

4. Save and Close the updated model.

If you did not previously make a backup copy of the old model, you can save the updated model under a new name to preserve the old model.

5. Verify that Your model Runs Under System Generator v9.1.01.

If you have followed the instructions in the previous steps, your model should run with System Generator v9.1.01. Open the model with System Generator v9.1.01 and run it.

Examples

Example 1:

```
>> xlUpdateModel('my_model_name');
```

Update the file `my_model_name.mdl` that is located in the current MATLAB working directory.

Example 2:

```
>> xlUpdateModel('my_model_name', 'lib');
```

Update the file `my_model_name.mdl` that is located in the current MATLAB working directory, along with the libraries that are associated with the model.

Example 3:

```
>> xlUpdateModel('my_model_name', 'assert');
```

Update the file `my_model_name.mdl` that is located in the current MATLAB working directory. Add **Assert** blocks where necessary.

Getting Started

Introduction

This Getting Started training consists of six short lessons that introduce you to major features of System Generator for DSP. Each lesson takes less than 10 minutes to read and is followed by one or more hands-on lab exercises. The lab exercise folders are located in the System Generator software tree and contain data files and step-by-step instructions.

If you have System Generator installed on your computer, you can complete each lab exercise at your own pace and on your own time schedule. If you do not have System Generator installed, you can access this free training in a recorded e-learning format through the Xilinx web site at the following location:

<http://www.xilinx.com/support/training/rel/system-generator.htm>

The lessons contained in this Getting Started are as follows:

- **Lesson 1 - Design Creation Basics:** Introduces the basics of creating and implementing a DSP design using System Generator.
- **Lesson 2 - Fixed Point and Bit Operations:** Covers the use of the System Generator routing blocks for extracting and manipulating the individual bits of a fixed-point signal.
- **Lesson 3 - System Control:** Covers the preferred methods for using System Generator to create finite state machines, logical control conditions, and the handling of bursty data typical of FFT and filtering operations.
- **Lesson 4 - Multi-Rate Systems:** Shows the proper way to create multi-rate systems using upsampling and downsampling of data.
- **Lesson 5 - Using Memories:** Covers proper usage of the Xilinx block RAM resources and the DSP blocks available for building DSP designs targeting Xilinx RAMs.
- **Lesson 6 - Designing Filters:** Discusses methods for creating efficient FIR filters in the Xilinx devices, use of the FIR Compiler block for filter implementation, and use of the FDATool for filter design.

Lesson 1 - Design Creation Basics

The System Generator Design Flow

System Generator works within the Simulink model-based design methodology. Often an executable spec is created using the standard Simulink block sets. This spec can be designed using floating-point numerical precision and without hardware detail. Once the functionality and basic dataflow issues have been defined, System Generator can be used to specify the hardware implementation details for the Xilinx devices. System Generator uses the Xilinx DSP blockset for Simulink and will automatically invoke Xilinx Core Generator™ to generate highly-optimized netlists for the DSP building blocks. System Generator can execute all the downstream implementation tools to product a bitstream for programming the FPGA. An optional testbench can be created using test vectors extracted from the Simulink environment for use with ModelSim or the Xilinx ISE™ Simulator.

The SysGen Design Flow

The Xilinx DSP Blockset

The Xilinx DSP blockset is accessed via the Simulink Library browser which can be launched from the standard MATLAB toolbar. The blocks are separated into sub-categories for easier searching. One sub-category, "Index" includes all the block and is often the quickest way to access a block you are already familiar with. Over 90 DSP building blocks are available for constructing your DSP system.

The Xilinx DSP Blockset

- Over 90 DSP building blocks available
- Blocks are accessed through the Simulink Library Browser
 - This can be launched from the MATLAB toolbar

Defining the FPGA Boundary

System Generator works with standard Simulink models. Two blocks called “Gateway In” and “Gateway Out” define the boundary of the FPGA from the Simulink simulation model. The Gateway In block converts the floating point input to a fixed-point number. You double-click on the block to bring up the properties editor which is where the fixed-point number can be fully specified.

Defining the FPGA Boundary

- The FPGA boundary is defined by the Xilinx “Gateway In” and “Gateway Out” blocks
- The “Gateway In” block converts the floating-point input to fixed-point
 - Saturation and rounding modes are defined
- The “Gateway Out” block converts the FPGA outputs back to double precision

Adding the System Generator Token

Every System Generator diagram requires that at least one System Generator token be placed on the diagram. This token is not connected to anything but serves to drive the FPGA implementation process. The property editor for this token allows you to specify the target netlist, device, performance targets and system period. System Generator will issue an error if this token is absent.

Adding The System Generator Token

- Every design must include a System Generator Token
- Sets the global netlisting options required for FPGA implementation
 - Target device
 - VHDL / Verilog RTL
 - Clock performance requirements
 - Downstream toolflow

Each System Generator must include the "System Generator" Token

The Simulink System Period must be set correctly for simulation to work

Creating the DSP Design

Once the FPGA boundaries have been established using the Gateway blocks, the DSP design can be constructed using blocks from the Xilinx DSP blockset. Standard Simulink blocks are not supported for use within the Gateway In / Gateway out blocks. You will find a rich set of filters, FFTs, FEC cores, memories, arithmetic, logical and bitwise blocks available for use in constructing DSP designs. Each of these blocks are cycle and bit accurate.

Creating the DSP Design

- All the blocks in the Xilinx DSP blockset are available for creating DSP designs targeting FPGAs
 - Over 90 blocks are available
 - Basic building blocks such as arithmetic and logical operators
 - Complex IP such as FIR filters, FFTs and FEC blocks
- These blocks leverage Xilinx IP generators to produce optimal results for Xilinx devices

Generating the HDL Code

Once the design is completed, the hardware implementation files can be generated using the **Generate** button available on the System Generator token properties editor. One option is to select **HDL Netlist** which allows the FPGA implementation steps of RTL synthesis and place and route to be performed interactively using tool specific user interfaces. Alternatively, you can select **Bitstream** as the Compilation target and System Generator will automatically perform all implementation steps.

Generating the HDL Code

Once complete, double-click the System Generator token

- Select **HDL Netlist** as the compilation mode
- Select the target part
- Set HDL language
- Set the **FPGA Clock Period**
- Check **Create Testbench**
- **Generate** the HDL

If the **Create Testbench** option is selected, then System Generator will save and write test vector files that are extracted from the Simulink simulation and generate an HDL testbench and script files for ModelSim. This is an optional step that simply verifies that the generated hardware is functionally equivalent to the Simulink simulation. The script files must be used with ModelSim interactively.

Model-Based Design using System Generator

Model-based design refers the design practice of creating a high-level executable specification using the standard Simulink blocksets or MATLAB first to define the desired functional behavior with minimal hardware detail. This executable spec is then used as a reference model while the hardware representation is specified using the Xilinx DSP blockset.

Model-Based Design using System Generator

- System Generator extends the model based design environment of Simulink for FPGA Design
 - First develop a high-level executable spec using standard Simulink blocks
 - Create an FPGA specific implementation using System Generator
 - Use Simulink to compare for functional and fixed-point differences

Creating Input Vectors using MATLAB

Simulink is built on top of MATLAB allowing the use of the full MATLAB language for input signal generation and output analysis. You can use the "From Workspace" and "To Workspace" blocks from the Simulink Source and Sink libraries. Input values must be specified as an n rows x 2 column matrix where the first column is the simulation time and the second column includes the input values. This is a very popular way to generate input vectors for System Generator designs.

Creating Input Vectors using MATLAB

- The Simulink "From Workspace" block provides a convenient way to generate input stimulus for Simulink designs

- Data must be in the form of a 2xn matrix
 - Column 1 = time values
 - Column 2 = data values
- Often this is a more descriptive approach and does not require sourcing a MATLAB file prior to simulation

Lesson 1 Summary

- You partition the FPGA design from the Simulink “system” using Gateway In / Gateway Out blocks.
- You always include a System Generator token on each sheet
- You should only use blocks from the Xilinx DSP blockset between the gateway blocks
- You should consider using the From / To workspace blocks to use MATLAB for input generation and output analysis

Lab Exercise: Using Simulink

In this lab, you will learn the basics of Simulink. You will use a Simulink blockset to generate a simple design and take it through simulation. You will then change the sampling settings to see its effect on the output. You will then learn how to create a subsystem.

The lab instructions are located in the System Generator software tree at the following pathname:

...<sysgen_tree>/examples/getting_started_training/lab1/lab1.pdf

Lab Exercise: Getting Started with System Generator

This lab introduces you to the basic concepts of creating a design using System Generator within the model-based design flow provided through Simulink. The design is a simple multiply-add circuit.

The lab instructions and lab design are located in the System Generator software tree at the following pathname:

...<sysgen_tree>/examples/getting_started_training/lab2/

Lesson 2 - Fixed Point and Bit Operations

Fixed-Point Numeric Precision

System Generator supports three data types, **Unsigned** for positive only DSP operations, **Signed** which is two's complement used for DSP operations that involve negative numbers and **Boolean** for 1-bit control signals. Each block will typically have quantization parameters. The initial quantization is defined by the Gateway In blocks.

Fixed-Point Numeric Precision

- The Xilinx "Gateway In" block will convert the Simulink "double" datatype to fixed-point numeric precision
 - Fixed-point arithmetic trades off numerical precision for hardware efficiency
- System Generator supports unsigned (ufixed) and two's complement (fixed)
 - Use "fixed" for negative numbers
 - Reduced dynamic range

UNSIGNED

Decimal	Bit Pattern
15	1111
14	1110
13	1101
12	1100
11	1011
10	1010
9	1001
8	1000

-5	1011
-6	1010
-7	1001
-8	1000

System Generator Fixed-Point Quantization

Xilinx fixed-point data types are defined by specifying the total number of bits then specifying the location of the binary point. The difference, which represents the number of bits to the left of the binary point, are the integer bits for unsigned numbers and the integer bits plus sign bit for signed numbers. Xilinx FPGAs do not require that fixed-point numbers fall in pre-defined 8 bit boundaries as is the case with DSP processors. The logic can grow bit-by-bit to accommodate the required fixed-point precision.

System Generator Fixed-Point Quantization

- System Generator supports the following fixed-point data types
 - Signed (2's Complement)
 - Required for negative numbers
 - Unsigned
 - Provides a greater range with same hardware when numbers are all positive
- To optimize the dynamic range of a number
 - Use a minimal # of integer bits to accommodate the range of possible values
 - Use a minimal # of fraction bits to accommodate acceptable precision

Fractional Bits	Fractional Values Available
1	0, 0.5
2	0, 0.25, 0.5, 0.75
3	0.125, 0.25, 0.375, 0.5, 0.625, 0.75, 0.875

Overflow and Round Modes

System Generator supports the overflow modes **Wrap**, **Saturate** and **Flag as error**. **Wrap** is the default because it has the least cost in hardware. **Saturate** requires System Generator to insert logic to perform that operation and therefore should only be used when necessary for the application.

System Generator supports **Truncate** and **Round** of the LSB during the quantization process. Similar to the **Wrap** mode for overflow mode, **Truncate** has minimal hardware cost and is the default. Specifying the **Round** mode requires System Generator to insert extra logic and should be used when only necessary for the application.

Overflow and Round Modes

Overflow

- Defines how System Generator handles the MSB of a number
 - When a number is too large to be represented by the integer bits of a number
- Wrap – the MSB's are dropped
 - Simple to implement in hardware
- Saturate – The result is set to the maximum value
 - Requires additional logic

Round Mode

- Defines how System Generator handles the LSB of a number
 - When a floating-point number is converted to fixed-point, "unnecessary" precision is lost
- Users must decide to "cut the precision off" (truncate) or to round to the nearest precision value (round)

Bit-Level Operations

In a real DSP hardware system, not all operations can be expressed mathematically. Often a signal must be accessed by its individual bits. System Generator supports a set of bit-level operations that allow the reinterpret, combining, conversion and extraction of the individual bits of a signal. This can be used to pad, unpad and slice off the bits of a signal with a high degree of control. These blocks do not use any hardware resources

Bit-level Operations

- Implementing a DSP design in hardware will typically require some operations to be performed at the bit level
- System Generator support blocks to perform the following bit-level operations:
 - **Reinterpret** unsigned data as signed or the converse
 - **Combine** two data buses together to form a new bus
 - **Convert** a fixed-point data type to a new fixed-point data type
 - **Extract** certain bits of data, especially when there is bit growth

The Reinterpret Block

The Reinterpret block forces the bits of a signal to a new type without regard for the numerical value or location of the decimal point. This block does not change the number of bits of a signal but simply reinterprets the data type. For example if the number 4 is represented as an unsigned [4 1] it is 1000. If this number is reinterpreted to be unsigned [4 0], the 1000 is now 8.

Reinterpret Block

- Forces the output to a new type without regard for the numerical value represented by the input
- The total number of bits in = total number of bits out
- Allows unsigned data to be reinterpreted as signed data and the converse
- Allows scaling of the data through repositioning of the binary point
 - '1000' quantized to unsigned [4 1] = 4
 - '1000' reinterpreted to unsigned [4 0] = 8

The Convert Block

The Convert block changes the quantization of a number but not the value. This block can alter the number of bits used to represent a number. It can be used to convert a signed type to an unsigned type and visa versa. Often the Convert block is used to truncate the output fractional bits after a multiplication operation.

Convert Block

- converts each input sample into a number of a desired arithmetic type
 - Converts a number to a signed (twos complement), unsigned value, or Boolean
 - The total number of bits and the binary point are user specified
 - Overflow and quantization options apply to the output value

The Concat Block

The Concat block concatenates two inputs into a single output at the bit level. This block has two input ports that are labeled *hi* and *lo*. The *hi* port occupies the MSB's and the *lo* input occupies the LSB's of the output signal. This block is useful for zero padding the MSBs or LSBs of a signal.

Concat Block

- concatenates two inputs up to 16 bits
- All inputs must be unsigned integers
 - That is, unsigned numbers with binary points at position zero
- The Reinterpret block provides signed-to-unsigned conversion capabilities that can extend the functionality of the concat block

Slice Block

The Slice block is used to access individual bits of a quantized number. This block provides several mechanisms by which the sequence of bits can be specified. If the input type is known at the time of parameterization, the various mechanisms do not offer any gain in functionality. If, however, a Slice block is used in a design where the input data width or binary point position are subject to change, the variety of mechanisms becomes useful. For example, the block can be configured to always extract only the top bit of the input, or only the integer bits, or only the first three fractional bits.

Slice Block

- Slices off a sequence of bits from the input data to create a new data value
- The output data type is unsigned, with its binary point at zero
 - One bit slices can be set to type “boolean”

The BitBasher Block

The BitBasher block provides a textual method, based on Verilog syntax, for working with the signals at the bit level. This block supports concatenation and slicing if the input signal to create an output. It also allows for augmentation with constants. The BitBasher block supports up to 4 outputs that are inferred by the expressions

BitBasher Block

- Bit manipulation and augmentation through textual specification
 - Based on Verilog syntax
 - Supports Concatenation, Slicing and Repeat operators
 - Allows augmentation with constants specified as binary, decimal, octal or hex
 - At least one of the inputs must be from input port
 - Supports up to four outputs
 - Number of Output type and Binary point fields available in Output Type tab depends on number of output equations in Basic tab

Lesson 2 Summary

- Quantization and overflow options are available when the output of a block is user defined
- Quantization occurs when the number of fractional bits is insufficient to represent the fractional portion of a value
- Overflow occurs when a value lies outside the representable range
- Bit picking blocks allow combining of multiple buses into a single bus, force a conversion of data type without changing the number of bits, extract bits, and convert the number into different format
- The BitBasher block allows bit manipulation and augmentation through textual specification based in Verilog

Lab Exercise: Signal Routing

In this lab you will design and verify padding and unpadding logic using the System Generator signal routing blocks

The lab instructions are located in the System Generator software tree at the following pathname:

```
...<sysgen_tree>/examples/getting_started_training/lab3/lab3.pdf
```

Lesson 3 - System Control

Controlling a DSP System

When you develop a DSP system in hardware, some level of control is usually required. This may include state dependent behavior or simply performing operations such as filter coefficient updating. System-level control may also be needed for controlling bursty data such as non-streaming FFTs.

Controlling a DSP System

- Real hardware will require some level of operational System control
- System Generator supports the following control mechanisms
 - Finite State Machines
 - Bursty data flow control
 - Reset and Clock Enable pins
 - Logical expressions

The MCode Block

The MCode block supports the use of MATLAB for implementing state dependent and branch conditional control operations. This block is not suitable for MATLAB that describes an algorithmic operation such as a FIR filter or Matrix inverse. The Xilinx AccelDSP™ Synthesis Tool can be used in these cases. The MCode block provides a convenient and efficient method for implementing state machines and complex muxing conditions. This is the recommended way to implement a finite state machine in System Generator.

The MCode Block

- System Generator includes an “MCode Block” that supports using MATLAB for modeling low-level hardware control structures
 - MATLAB is translated in VHDL during hardware generation
 - The MCode block does not support algorithmic MATLAB - use AccelDSP
- Recommended for implementing state machines in System Generator
 - A state variable is declared with the MATLAB keyword *persistent* and must be initially assigned with an *xl_state* function call
- Restrictions
 - All block inputs and outputs must be Xilinx fixed-point type
 - The block must have at least one input port and one output port

```
function q = accum(din, rst)
init = 0;
persistent s, s=xl_state(init, xLSigned,4,0);
q=s;
if rst
    s=init;
else
    s=s+din;
end
```

The Xilinx “xl_state” Data Type

When implementing a state machine using the MCode block, a Xilinx-provided MATLAB function called “xl_state” must be used to initialize a persistent variable. This function has two arguments, the first is the initial condition, the second is the quantization of the assigned variable. For example, if your state machine has 6 states, you need a quantization of 4-bits unsigned.

The Xilinx “xl_state” Datatype

- “xl_state” is a Xilinx provided MATLAB datatype that can be used with the MCode Block to specify FSM state variables
 - Vectors specified with “xl_state” will be efficiently implemented hardware
 - `v = xl_state(init, precision)`
 - Init = initial value of state register after reset
 - Precision = a Xilinx fixed-point datatype defined for the MCode block:
 - `xlUnsigned(<word length>, <binary point>)`
 - `xlSigned(<word length>, <binary point>)`

State Machine Example

The figure below shows a simple 2-state FSM. This can be easily extended to more states. Notice that a variable called "state" is declared to be persistent and is initialized to 2 bits, unsigned using the "xl_state" function. A switch-case statement is then used to decode the inputs, branch to the next state and assign the outputs.

State Machine Example

- The following simple FSM example shown how the MCode block can be used to implement a finite state machine
- This example can be easily extended to include more complex behavior

```

function [out1] = fsm(in1)

persistent state,
state=xl_state(0,{xlUnsigned,2,0});

switch double(state)
case 0
    if in1==1;
        out1=0;
        state=1
    else
        out1=0;
        state=0;
    end
case 1
    if in1==0
        out1=1;
        state=0;
    else
        out1=0;
        state=1;
    end
otherwise
    state=0;
    out1=0;
end
end
  
```

The Expression Block

The Expression block performs a bitwise not, and, or & xor on two input signals. The inputs can have a word length greater than 1. In cases where the two inputs have different word lengths, the binary points are matched up and then an element-by-element boolean operation is performed. This block provides a useful way to implement logical control in a DSP system

The Expression Block

- The expression block provides an easy way to implement logical control using expressions
- Number of input ports is inferred from the expression
 - “a & b | c” = 3 inputs

Operator	Symbol
Precedence	()
NOT	~
AND	&
OR	
XOR	^

Reset and Enable Ports

Most System Generator blocks that include memory or storage provide options to expose the reset and clock enable ports. If un-selected, these ports are automatically connected to the final hardware's global reset and clock enable or DCM schemes. Exposing these ports on the System Generator block creates a condition where the block is reset or enabled when either the global signals or the local signals assert TRUE. You should use these ports if greater control over these functions is required in the DSP system.

Reset and Enable Ports

- System Generator blocks that include storage generally offer the option to add a reset and clock enable pin
 - The signals driving these ports must be of type "boolean"

Bursty Data

Several of the more complex DSP blocks offered in the Xilinx DSP blockset result in “bursty” data. For example, the non-streaming FFT requires several clock cycles to process the input data prior to generating valid output data. In these cases, these blocks include data flow control ports that must be used in the DSP system. These ports provide basic push mode dataflow control. They consist of a `vin` port which indicates that valid data is available at the inputs and `vout` which indicates that valid data is available at the outputs.

Bursty Data

- Often the dataflow through the system is not continuous but rather comes in “bursts”
 - Non-streaming FFT
 - Resource shared FIR Filter
- In these cases the user will need to implement dataflow control into the System Generator diagram
- System Generator blocks that require extra data processing time will include two flow control ports called “vin” & “vout”

Blocks that have valid bit modeling :

- FIR (optional)
- FFT
- Reed-Solomon Encoder/Decoder
- Viterbi Decoder
- Convolutional Encoder
- Interleaver/DeInterleaver
- CIC

Lesson 3 Summary

- Use the MCode block for state machines and branch conditional logic
- Use the Expression block to implement logical control at the bit level
- Storage elements have the ability to include optional reset and clock enable pins that can be connected in System Generator
- Blocks that operate on bursty data include data flow control pins called `vin` and `vout`

Lab Exercise: System Control

In this lab you will be creating a simple state machine using the MCode block to detect a sequence of binary values "1011". The FSM needs to be able to detect multiple transmissions as well, i.e., "10111011"

The lab data and instructions are located in the System Generator software tree at the following pathname:

```
...<sysgen_tree>/examples/getting_started_training/lab4/
```

Lesson 4 - Multi-Rate Systems

Creating Multi-Rate Systems

The following illustration shows a typical base-station receiver. The tower has multiple antennas to provide sector coverage of the area. The diagram shows that this results in two receiver channels. In each of these channels, there is some form of complex mixing, resulting in real and imaginary channels.

Often DSP systems such as this will down sample the input signals prior to the digital filtering steps performed during equalization and demodulation. Doing so can simplify the filter design and hardware significantly. These systems are referred to as “multi-rate” systems

Creating Multi-Rate Systems

- Down-sampling and up-sampling data through a DSP system is a common approach to improving hardware efficiency
 - A common example, shown below, is a wireless base station
- System Generator supports the design of multi-rate systems through rate changing blocks

Up and Down Sampling Blocks

System Generator includes Up Sample and Down Sample blocks that change the system sample rate. The Up Sample block adds additional samples to the signal to achieve the desired rate change. The value of these new samples is either zero or the value of the last actual sample depending on the block options. The Down Sample block simply discards samples until it achieves the desired rate change. For example, downsample by 3 means to discard 2 out of every 3 samples.

Up and Down Sampling Blocks

- Use the “Up Sample” and “Down Sample” blocks to change the rate of a signal in System Generator

- The **up sample** can either replicate the same number $M-1$ times or insert $M-1$ zeros to achieve the higher sampling rate

- The **down sample** “throws away” $M-1$ samples to achieve the lower sampling rate

Rate Changing Functional Blocks

In addition to the straightforward “Up Sample” and “Down Sample” blocks, System Generator also provides rate changing functional blocks; that is blocks that also perform a specific function. The Parallel to Serial block will up sample, the Serial to Parallel block will down sample, the FIR Compiler, if using a resource-shared multiplier will down sample and the TDM block will up sample.

Rate Changing Functional Blocks

- The following functional blocks will also change the rate of a DSP system

Parallel to Serial: The output rate will be M-times faster, where M is the width of the input parallel data	 Parallel to Serial
Serial to Parallel: The output rate will be M-times slower, where M is the width of the output parallel data	 Serial to Parallel
FIR and FIR Compiler: Can be used as a polyphase interpolation or decimation FIR	 FIR Compiler v1_0
The Time Division Multiplexer block multiplexes values presented at input ports into a single faster rate output. The up sample rate is determined by the number of input	 Time Division Multiplexer

Viewing Rate Changes in Simulink

Simulink supports viewing different sample times as different colors which is fully supported for System Generator blocks. To enable the **Sample Time Colors** feature, select the pulldown menu **Format > Sample Time Colors**. The Simulink tool does not automatically recolor the model with each change you make to it, so you must select **Edit > Update Diagram** to explicitly update the model coloration. To return to your original coloring, disable the sample time coloration by, again, choosing **Sample Time Colors**.

Viewing Rate Changes in Simulink

- Sample rates can be displayed in different colors using Simulink
 - Use the pull down menu command (**Format** → **Sample Time Colors**)
- The actual sample rate of a particular wire can be displayed using the “Sample Time” (ST) block in the Xilinx Blockset
 - Use the Simulink display block to view the output of the sample block
 - Does not add hardware to the design

System Generator provides 3 debugging utilities to assist in debugging complex multi-rate systems.

The `clk` probe is not connected to any inputs but only to a scope output. It displays the master clock. This can be used with the Clock Enable Probe to display the behavior of the clock enable signal at various points in the down sampling

- The “clk” probe and the “clock enable probe” can be used to view the behavior of the multi-rate system
 - These blocks add no logic
 - Their outputs can be connected directly to a Simulink sink block

Sample Period “Rules”

The illustration below is an example of a multi-rate system that demonstrates how the Simulink System Period can be calculated and entered into the System Generator token GUI.

If you get it wrong, there is a sampling period analyzer that automatically determines the appropriate sample period and prompts you to update the GUI.

Sample Period “Rules”

- The system period is the global sample period from which all other sample periods can be derived
 - The System Period is set in the System Generator token
- Every sample period in a design must be a multiple of the system period

Block Output	X	Up Sample	Down Sample
Sample Period	1	.5	1.5
Sample Period (GCD)	2/2	1/2	3/2

Lab Exercise: Multi-Rate Systems

In this lab you will be exploring the effects of the rate changing blocks available in System Generator. These blocks include Upsample, Downsample, Serial to Parallel and Parallel to Serial.

The lab instructions and lab design are located in the System Generator software tree at the following pathname:

...<sysgen_tree>/examples/getting_started_training/lab5/

Lesson 5 - Using Memories

Block vs. Distributed RAM

Xilinx FPGAs offer two distinct memory options, Block RAM and Distributed RAM. Block RAM uses dedicated, on-chip, hardware resources and represents the most area-efficient RAM implementation. Block RAMs offer high performance but due to their fixed location on the chip, may incur slightly larger routing delays. Distributed RAM uses the lookup tables in the FPGA slices to implement memory and in doing so will subtract from the slices available for logical operations. Because Distributed RAM can be located anywhere throughout the chip, routing delays can be minimized and slightly higher performance can be achieved. Distributed RAM is an excellent option for small FIFOs.

Block vs. Distributed RAM

- Xilinx devices offer two implementation options for RAMs, FIFOs and ROMs
 - Block RAM – uses dedicated on-chip RAM resources
 - More area efficient
 - Distributed RAM – uses the FPGA lookup tables
 - Higher performance
 - Subtracts from available area for logic
- System Generator RAM, FIFO and ROM blocks support either implementation

Distributed RAM/SRL16

- Very efficient, localized memory
- Minimal impact on logic routing
- Great for small FIFOs

On-chip BRAM/FIFO

- Efficient, on-chip blocks
- Flexible + optional FIFO logic
- Ideal for mid-sized FIFOs/buffers

Initializing RAMs and ROMs

The RAM and ROM blocks can be initialized to a 1xn vector that matches the depth of the RAM. MATLAB is used to set the initial value vector. Any MATLAB statement can be used that results in a 1xn vector including the file reading commands such as `imread`, `auread`, `wavread`, and `load`.

Initializing RAMs and ROMs

- MATLAB statements are used to initialize the RAMs and ROMs.
 - Statement must create a 1xn vector
- Loading a text file
 - `load('filename.txt')`
- Using a MATLAB statement
 - `sin(pi*(0:15)/16)`
- Reading other file formats
 - `imread`
 - `auread`
 - `aviread`
 - `wavread`
 - `fread`

System Generator RAM Blocks

System Generator provides both a single- and dual-port RAM block. Depths up to 64K are supported. Both Distributed RAM and Block RAM implementation options are available. System Generator calls the Xilinx memory compiler to create an efficient memory structure in hardware for the given parameters, bit widths and depths. You don't need to be concerned with the hardware details of the specific Virtex™ block or Distributed RAM structure. Both the single- and dual-port RAM blocks support initialization. The signal connected to the address port of a RAM must be unsigned with no fractional bits.

System Generator RAM Blocks

- System Generator offers both single and dual port RAM blocks
 - Options include selection of “Block” vs. “Distributed” implementation options
- These blocks call the Xilinx IP memory generator to create efficient RAM implementations for any depth and bit widths

System Generator ROM Blocks

The ROM block supports an implementation in either Block- or Distributed RAM and is initialized through a MATLAB command. The signal connected to the address port must be unsigned with no fractional bits

System Generator ROM Blocks

- Offers both Block RAM vs. Distributed RAM implementation Options
- Address port must be unsigned with no fractional bits
- Depth and data widths are user configurable

The Delay Block

The Delay block is used to synchronize dataflow through the FPGA. This block maps to a highly-efficient shift register structure built from a slice lookup table called an SRL16 that is 85% smaller than using registers.

The Delay Block

- Use the Delay block to synchronize the dataflow of signals through the design
- The implementation will be constructed from “SRL16E” primitives
 - Highly efficient use of the Virtex distributed RAM for implementing delay elements and shift registers

SRL16E Structure

The FIFO Block

The FIFO block supports both Block RAM and Distributed RAM implementations. Depths up to 64K are supported. Three output flags are supported, `empty`, `full` and `%full`. The `%full` flag is set depending on a bit width specification. One bit will be zero until the FIFO is 50% full, then it will set to .5. Two bits will be zero until 20% full, then .25, .5 and .75.

The FIFO Block

- Can be implemented in either Block or Distributed RAM
- Supports FIFO depths up to 64K
- Supports a “full” and “percentage full” output signals
 - %full Specified as number of bits
 - Unsigned, fractional
 - 1 bit shows <50% or >50% full
 - 2 bits show 25% full increments
- Includes optional reset and clock enable ports

Lab Exercise: Using Memories

In this lab you will learn how to use a Xilinx ROM block to implement a LUT-based operation such as an Arcsin using Block RAM or Distributed RAM. This provides an efficient implementation for trig and math functions with inputs that can be quantized to 10 bits or less.

The lab instructions and lab design are located in the System Generator software tree at the following pathname:

```
...<sysgen_tree>/examples/getting_started_training/lab6/
```

Lesson 6 - Designing Filters

Introduction

Digital filters are a common DSP operation and especially well suited to implementation in FPGAs. High-performance applications benefit greatly from parallel filters that can return a results on every clock cycle. The Virtex™- 5 device includes up to 550 parallel multipliers. The FIR Compiler is designed to use these multipliers in the most efficient manner for creating commonly used FIR filters. An alternative implementation is available called “distributed arithmetic” that creates FIR filters without using multipliers by employing a shift-add technique. This can be used for smaller devices when the available multipliers have been allocated to other functions.

Introduction

- Digital filters are the most common functions found in DSP systems
- The following blocks are supported by System Generator for digital filtering
 - FIR Compiler block (DSP Blockset)
 - DAFIR block (DSP Blockset)
 - CIC block (Reference Designs Blockset)
- The digital filtering technique will depend on several factors
 - Sample rate
 - Sample width
 - Profile of the coefficients
 - Clock rate
 - Technological resources

The Virtex DSP48 Math Slice

The Virtex™ family introduces a high-performance arithmetic unit along with a multiplier: the low-power DSP48 slice. The following figure is a detailed diagram of the DSP48 structure. The DSP48 slice consists of four main sections: (1) I/O registers, (2) signed multiplier, (3) three-input adder/subtractor, and (4) OPMODE multiplexers.

The Virtex DSP48 Math Slice

- The Virtex4 & 5 devices include up to 550 DSP48 slices
 - Performs 48 unique math operations common to DSP operations
 - Configuration set through an “opcode” input
- Efficient use of DSP48 slice is required to get high performance and efficient filters

Virtex4 DSP48 Math Slice

Virtex5 DSP48 Math Slice

FIR Compiler Block

The Xilinx Fir Compiler v1_0 block implements a high speed MAC based FIR filter. It accepts a stream of input data and computes filtered output with a fixed delay, based on the filter configuration. The FIR Compiler supports generation of resource shared or parallel FIR structures and polyphase decimation and interpolation structures. Also supported is oversampling. Coefficients are specified using MATLAB commands.

FIR Compiler Block

- The Xilinx Fir Compiler block implements a high speed MAC based FIR filters using DSP48 primitives
- Supports polyphase decimation, polyphase interpolation and over sampling implementations

Creating Coefficients with FDATool

The Mathworks FDATool is a graphical filter design program that can be used to generate coefficients for the FIR Compiler block.

Creating Coefficients with FDATool

- Enables the use of The Mathworks FDATool for creating filter coefficients graphically
- Coefficients can be “exported” to either the MATLAB workspace or a text file

Using FDA Tool Coefficients

Once a suitable filter response has been designed, you simply export the coefficients to the workspace using the **File > Export** command. The workspace variable can then be referenced in the FIR Compiler properties editor

Using FDA Tool Coefficients

Lab Exercise: Designing Filters

In this lab you will be using the Filter Compiler block to generate optimized filters for the Virtex™-4 architecture.

The lab instructions and lab design are located in the System Generator software tree at the following pathname:

```
...<sysgen_tree>/examples/getting_started_training/lab7/
```

Additional Examples and Tutorials

Numerous examples are used to illustrate System Generator features and functions in the System Generator documentaton. These examples are found in the directory at pathname <sysgen_tree>/examples and are listed in the table below. In addition to these examples, System Generator also includes demonstration models that can be run from the demo page. Enter the following command at the MATLAB prompt:

```
demo blocksets xilinx
```

Note: If you are using the MATLAB help browser you can open and run the examples directly from this page. To run an example, click on the link. MATLAB will change directories to the example directory and open the example model.

Black Box Examples

Topic	Description
Importing a VHDL Module	A tutorial showing how to use the black box to import VHDL into a System Generator design and how to use ModelSim to co-simulate the VHDL module.
Simulating Several Black Boxes Simultaneously	Shows how black boxes can co-simulate simultaneously, using only one ModelSim license.
Dynamic Black Boxes	A tutorial showing how to parameterize the black box.
Importing a Verilog Module	A tutorial showing how to use the black box to import Verilog into a System Generator design and how to use ModelSim to co-simulate the Verilog module.
Importing a Xilinx Core Generator Module	A tutorial showing how to import a COREGEN module as a black box.

ChipScope Examples

Topic	Description
Using ChipScope Pro Analyzer for Real-Time Hardware Debugging	This tutorial demonstrates how to connect and use the Xilinx Debug Tool called ChipScope™ Pro within Xilinx System Generator. The integration of ChipScope Pro in the System Generator flow allows real-time debugging at system speed.

DSP Examples

Topic	Description
DSP48 Block	Simple example demonstrating the use of the DSP48 block with the Constant block used to provide the DSP48 instruction.
DSP48 Macro Block	Simple example demonstrating how to use a DSP48 Macro block to implement a Complex Multiplier.
DSP48 Block (35-Bit Multiplier using DSP48 and Constant block)	This design demonstrates the use of the DSP48 and Constant block in implementing 35 by 35-bit multipliers at different sample rates. Three multipliers implementations are shown at 1, 2, and 4 clocks per sample.
DSP48 Macro Block (FIR filter using the DSP48 Macro block as a multiply accumulate function)	This design demonstrates the use of the DSP48 Macro block in implementing a 35 by 35 Multiplier.
DSP48 Block FIR filter examples using DSP48 block	This design demonstrates the use of the DSP48 and Constant block in FIR filter implementation. The design includes sets of parallel, semi-parallel and sequential FIR filter using Type 1 and Type 2 architectures. Each filter implements a 16-tap dsp48-based FIR filters.
DSP48 Design Techniques (DSP48-based dynamic shifter)	This design demonstrates the use of the DSP48 block in implementing a 35-bit signed right shift using 2 DSP48s.
DSP48 Design Techniques (Synthesizable FIR filter for Virtex™-4)	This design demonstrates how to use System Generator to implement a synthesizable FIR filter which maps efficiently to the Virtex™-4 architecture.
DSP48 Macro Block (FIR filter using the DSP48 Macro block as a multiply accumulate function)	This design demonstrates the use of the DSP48 Macro block when implementing a sequential FIR filter.
MAC FIR filter	This design example implements a 43 tap FIR Filter with a MAC engine and a Dual Port Ram used for data and coefficient storage.
Complex FIR filter	This example demonstrates a complex FIR filter built out of blocks from the System Generator and Simulink library.

M-Code Examples

Topic	Description
Simple Selector	This example shows how to implement a function that returns the maximum value of its inputs.
Simple Arithmetic Operations	This example shows how to implement simple arithmetic operations.
Complex Multiplier with Latency	This example shows how to build a complex multiplier with latency.
Shift Operations	This example shows how to implement shift operations.
Passing Parameters into the MCode Block	This example shows how to pass parameters into a MCode block.
Optional Input Ports	This example shows how to implement optional input ports on an MCode block.
Finite State Machines	This example shows how to implement a finite state machine.
Parameterizable Accumulator	This example shows how to build a parameterizable accumulator.
FIR Blocks and Verification	This example shows how to model FIR blocks and how to do system verification.
RPN Calculator	This example shows how to model a RPN calculator – a stack machine.
Example of disp function	This example shows how to use the disp function.

Processor Examples

Topic	Description
Designing and Exporting MicroBlaze Processor Peripherals	Demonstrates how to export a design from System Generator into Xilinx Platform Studio (EDK) by showing how to design a peripheral (pcore) for a MicroBlaze™ processor. An RGB to gray-scale color space converter is created and generated into a pcore using the Export to EDK compilation target.

Topic	Description
Tutorial Example - Designing and Simulating MicroBlaze Processor Systems	Demonstrates how to import a MicroBlaze processor created using Xilinx Platform Studio into System Generator. A DSP48 block is used as a co-processor to the MicroBlaze.
Designing PicoBlaze Microcontroller Applications	Demonstrates how to implement a PicoBlaze™ program in System Generator. The example programs the PicoBlaze to alter the output frequency of a Direct Digital Synthesizer (DDS) during an interrupt.

Shared Memory Examples

Topic	Description
Simulation across various models	Illustrates shared memories communicating across Simulink models.
Host PC Shared Memory access	Developer studio project to communicate with a shared memory.
High Speed Video Processing using Hardware Co-simulation	Discussion of a high-speed co-simulation buffering interface followed by an example in which the interface is used to support real-time processing of a video stream using a 5x5 filter kernel.
High speed I/O Buffering	Illustrates high speed Shared Memory I/O Buffering Interface for Hardware Co-simulation.
SharedMemory (Mex-function interface)	Illustrates the use of a mex-function as an interface to a shared memory.
Generating Multiple Cycle-True Islands for Distinct Clocks	An example using two asynchronous clocks.
Shared Memory, To FIFO, To Register, From Register	Demonstrates use of shared memories, FIFOs and registers to pass information.
Frame-Based Acceleration using Hardware Co-Simulation	Explains how to use frame or vector-based transfers to further accelerate simulations using FPGA hardware co-simulation.

Timing Analysis Examples

Topic	Description
Timing Analysis Tutorial	Explains how to use the System Generator Timing Analysis tool to meet timing requirements of System Generator designs. Also touches on techniques that may be used when a design does not meet timing.

Miscellaneous Examples

Topic	Description
Importing a System Generator Design into a Bigger System	Discusses how to take the VHDL netlist from a System Generator design and synthesize it in order to embed it into a larger design. Also shows how VHDL created by System Generator can be incorporated into simulation model of the overall system.
Configurable Subsystems and System Generator	Illustrates the use of Configurable Subsystems for Simulation and Generation.
Integrator	This example uses an integrator to illustrate error analysis capability.
Block RAM-Based State Machines	Demonstrates use of Mealy State Machine block from the reference library.

System Generator Demos

System Generator for DSP provides the capability to model and implement high-performance DSP systems in field-programmable gate arrays (FPGAs) using Simulink. The Xilinx Blockset contains bit and cycle-true models of arithmetic and logic functions, memories, and DSP functions for digital filtering, spectral analysis, and digital communications. System Generator converts a Simulink model of Xilinx blocks into an efficient hardware implementation that combines synthesizable VHDL and intellectual property blocks that have been hand-crafted to run efficiently in FPGAs.

Included with the tool are numerous demonstration designs that highlight key features and tool capabilities, as well as general good design practices using real-world design applications. These designs may be accessed from the System Generator demo page. Enter the following command at the MATLAB prompt:

```
demo blocksets xilinx
```
